Crystal chemistry of titanian chondrodite and titanian clinohumite of high-pressure origin[1]

KIYOSHI FUJINO[2] AND YOSHIO TAKÉUCHI

Mineralogical Institute, Faculty of Science
University of Tokyo, Hongo, Tokyo 113, Japan

Abstract

The crystal structures of titanian chondrodite [$Mg_{3.89}Fe_{0.87}Mn_{0.01}Ni_{0.01}Ti_{0.42}(SiO_4)_2OH_{1.15}O_{0.85}$; a = 4.7271(7), b = 10.318(1), c = 7.9053(9)A, α = 109.333(8)°, $P2_1/b$, Z = 2] and titanian clinohumite [$Mg_{7.44}Fe_{1.09}Mn_{0.02}Ni_{0.02}Ti_{0.43}(SiO_4)_4OH_{1.14}O_{0.86}$; a = 4.745(1), b = 10.283(2), c = 13.699(3)A, α = 101.00(2)°, $P2_1/b$, Z = 2] from the Buell Park (Arizona) kimberlite have been refined by full-matrix least-squares methods to R = 0.035 and 0.026, respectively. The results have established that Ti in the both structures is exclusively concentrated in the $M(3)$ site located in Mg(OH)O layers. This situation explains the fact that attainable substitution of Ti for Mg in chondrodite is higher than that in clinohumite.

The final difference Fourier synthesis of titanian clinohumite has brought out hydrogen positions, H and H′, which are related to each other by inversion, the separation between H and H′ being 0.87A, and O–H = 1.02A. This feature implies that if the positions were fully occupied by hydrogen atoms as in the OH end-member, there would arise a strong hydrogen-hydrogen repulsion. The substitution, Mg + 2(OH) → Ti + 2(O), that reduces the number of OH groups in the structure, would therefore play a role in reducing the effect of repulsion to stabilize the structure, thus explaining the non-occurrence in nature of OH end-members of the humite-group minerals; the substitution of F for OH would then play the same role.

Introduction

The minerals of the humite group are known so far to occur typically in metamorphosed and metasomatised limestones and dolomites and in skarns associated with ore deposits at contacts with acid plutonic rocks. Recently, McGetchin *et al.* (1970) pointed out that titanian clinohumite in the Moses Rock kimberlite had possibly equilibrated in the upper mantle at depths ranging from about 50 to 150 km at modest temperatures, generally less than 1000°C.

In experimental investigations under high pressure of the system MgO–SiO_2–H_2O, Yamamoto and Akimoto (1974, 1977) synthesized crystals of hydroxyl–clinohumite and –chondrodite at pressures between 29 and 77 kbar and temperatures between 700 and 1200°C. This suggested that clinohumite and chondrodite might be stable between 70 and 120 km depth in the upper mantle, and in fact Aoki *et al.* (1976) discovered titanian chondrodite and clinohumite in the Buell Park (Arizona) kimberlite, and gave a detailed account of the petrological significance of these minerals.

The present paper is a crystallographic counterpart of the investigation of these high-Ti minerals. Robinson *et al.* (1973) suggested a random distribution of Ti among octahedral positions, whereas Kocman and Rucklidge (1973) found Ti exclusively concentrated in the "Mg(OH,F)O layers", the notation of which was initiated by Ribbe *et al.* (1968) to substitute for "$Mg(OH,F)_2$ layers" in the humite group minerals. Our materials are suited to resolve this conflict because of their high Ti contents.

Material

Crystals of titanian chondrodite and clinohumite (abbreviated Ti–Ch and Ti–Cl, respectively) used in our study were collected from the heavy-mineral con-

[1] According to the suggestion made by Dr. A. Kato, chairman, Commission on New Minerals and Mineral Names, National Science Museum, Tokyo, Japan and Dr. C. A. Francis, Department of Geological Sciences, Virginia Polytechnic Institute and State University, we use in this paper the terminology titanian chondrodite and titanian clinohumite instead of titanochondrodite and titanoclinohumite to express Ti-bearing chondrodite and clinohumite respectively.
