### Abstract

The crystal structures of an albite sample from Tiburon, Marin County, California, annealed at 1080°C for 60 days, were refined from X-ray intensity data collected at 25, 500, 750, 980, and 1040°C to *R* factors of 0.034, 0.036, 0.037, 0.037, and 0.039 for 2443, 1993, 2013, 2016, and 2018 reflections, respectively. The crystal structures of a second albite sample from Amelia, Virginia, annealed at temperatures up to 1110°C for 133 days, were also refined to *R* factors of 0.040 and 0.044 based on 2018 and 430 reflections collected at 980 and 1060°C respectively.

The Tiburon sample failed to attain monoclinic symmetry with respect to either unit-cell dimensions or atomic parameters within the temperature range of study, which is in agreement with an earlier high-temperature investigation by Prewitt *et al.* (1976). Extrapolation of monoclinic indicators based on atomic positions and bond lengths related by pseudo-monoclinic symmetry indicates that monoclinic symmetry would be attained within the temperature range 1050–1075°C for the Tiburon sample and 1105–1110°C for the synthetic albite sample studied by Prewitt *et al.* (1976). The Amelia sample was found to be definitely monoclinic at 980°C. The variable inversion temperatures of these albite samples reflect differences in the degree of Al/Si disorder created by the different annealing times and temperatures. These differences in Al/Si disorder are too slight to be measured by current indirect methods.

The spatial disorder associated with the sodium atom in high albite is attributed to the response of Na to differences in the local Al/Si configurations created by Al/Si disorder. Previous interpretations restricting the number of such configurations to four and assuming isotropic Na quarter-atoms are inadequate. Changes in the electron density distribution about the Na atom as a function of temperature reflect changes in the shape of the aluminosilicate cage surrounding Na as monoclinic symmetry is gradually approached with increasing temperature.

### Introduction

Since the first structural analyses of low and high albite were made by Ferguson *et al.* (1958), there have been several unresolved crystallographic problems with regard to the highly anisotropic electron density distribution of the Na atom in both structures, as well as the degree and effects of Al/Si ordering in the tetrahedral positions of the aluminosilicate framework. In addition, considerable controversy has arisen over analbite and the monoclinic → triclinic inversion in "completely" disordered struc-

tures. Excellent summaries of the extensive literature devoted to these problems may be found in Ribbe *et al.* (1969), Smith (1974), and Prewitt *et al.* (1976).

In a high-temperature study of low albite, Winter *et al.* (1977) have shown that the anisotropy of the Na atom in low albite is solely the result of thermal vibration. As the Na anisotropy is quite different in the ordered and disordered forms of albite, a knowledge of the properties of low albite is expected to aid the interpretation of a similar series of high-temperature refinements of the more complex high structural state. In addition to the Na behavior, in this paper we discuss the effects of Al/Si disordering on the thermal response of the crystal, as well as on the triclinic → monoclinic transformation.
