## Abstract

The crystal structure of a magnesium-rich carpholite with the chemical formula  $(\text{Mg}_{0.795}\text{Fe}_{0.203}^{2+}\text{Mn}_{0.002})\text{Al}_2\text{Si}_2\text{O}_6(\text{OH})_4$  and with the lattice constants  $a = 13.714(2)$ ,  $b = 20.079(2)$ ,  $c = 5.105(1)$  (space group *Ccca*) has been refined by the least-squares method using 1163 reflections measured on a computer controlled automatic single-crystal diffractometer, using monochromatic  $\text{MoK}\alpha$  radiation. The unweighted R-factor is 0.044. The structure very closely resembles that of ferrocapholite and Mn-carpholite, thus suggesting the likelihood of complete miscibility between the three end-members. The inter-atomic bond distances and angles of the  $\text{SiO}_4$ -tetrahedra and the  $\text{AlO}_6$ -octahedra further demonstrate the crystal-chemical similarities between pyroxenes and Mn-carpholites, thereby emphasizing the similarity in bonding in all carpholites.

## Introduction

The comparatively recent discoveries of a large number of Fe- and Mg-rich carpholites in different parts of the world and their characteristic occurrence in geological units subjected to high pressure/low temperature metamorphism has aroused the interest of mineralogists and crystallographers in their structure and crystal-chemical relationships. Though the chemical compositions of carpholites can be represented by the end-members manganocarpholite,  $\text{MnAl}_2\text{Si}_2\text{O}_6(\text{OH})_4$ , ferrocapholite,  $\text{FeAl}_2\text{Si}_2\text{O}_6(\text{OH})_4$ , and magnesiocarpholite,  $\text{MgAl}_2\text{Si}_2\text{O}_6(\text{OH})_4$ , it has been observed that carpholites occur preferentially as binary solid solutions, the third component being generally less than 5% (Mottana and Schreyer, 1977; Viswanathan and Seidel, 1979). In order to understand the nature of the solid solutions and the crystal-chemical relationships a knowledge of the structure of the end-members is necessary. MacGillavry *et al.* (1956) first defined the basic structural principles of carpholites by determining the structure of an iron-rich carpholite,  $(\text{Fe}_{0.8}^{2+}\text{Mg}_{0.2})(\text{Al}_{0.95}\text{Fe}_{0.05}^{3+})\text{Si}_2\text{O}_6(\text{OH})_4$ , by conventional film methods. Later Naumova *et al.* (1975) and recently Lindemann *et al.* (1979) determined the structure of an almost pure manganocarpholite by more modern automatic diffractometer methods, and arrived at almost identical results. Under these circumstances it was considered

relevant to determine the structure of the remaining end-member, magnesiocarpholite, and compare it with the others. Unfortunately good crystals of the almost pure magnesiocarpholite from central Crete (specimen 77/5, Viswanathan and Seidel, 1979) could not be obtained because it is finely intergrown with pyrophyllite and muscovite. Hence another magnesium-rich specimen which was collected by Dr. E. Seidel in southeast Sfinari, West Crete (specimen KRH 2, Viswanathan and Seidel, 1979) was chosen for structure determination.

## Experimental and results

A typical feature of most of the carpholite crystals is their acicular habit, often tending to become fibrous. The needle axis is parallel to the crystallographic *c* axis. Specimens containing such magnesium-rich carpholites sometimes show such fibers bent during tectonic deformation. Most of the single crystals examined under the microscope appear as if they are made up of such fibers. Precession photographs of such crystals invariably showed splitting of reflections because of lack of parallel alignment of the fragile needles. Precession photographs of the crystal finally selected for the structure determination did not show any such effects. It had a needle shape with an approximate triangular cross section, the lengths of the sides of the triangle being  $0.105 \times$

CALCULATED AND OBSERVED STRUCTURE FACTORS OF MG-CARPHOLITE
