

Laffittite, AgHgAsS_3 : crystal structure and second occurrence from the Getchell mine, Nevada

IZUMI NAKAI¹ AND DANIEL E. APPLEMAN

Department of Mineral Sciences
Smithsonian Institution
Washington, D.C. 20560

Abstract

Laffittite was found in a museum specimen labelled getchellite, from the Getchell mine, Humboldt County, Nevada. The mineral occurs in grains about 1 mm in maximum length as dark red crystals associated with orpiment, getchellite and realgar.

Laffittite, AgHgAsS_3 , is monoclinic, space group Aa , $a = 7.732(3)$, $b = 11.285(7)$, $c = 6.643(4)\text{\AA}$, $\beta = 115.16(3)^\circ$, $Z = 4$. The strongest lines in the X-ray powder pattern are $3.512(100)(200)$, $3.202(78)(031, \bar{1}31)$, $3.015(69)(002)$, $2.685(67)(\bar{2}31)$, $1.898(29)(\bar{1}33, \bar{2}33)$, $2.136(18)(231, \bar{3}31)$, $3.633(16)(111)$, $1.889(14)(\bar{4}11)$.

Single crystals were hydrothermally synthesized at 350°C under 10,000 psi pressure for 140 hours. The starting material was a fused mixture of Ag_2S , HgS and As_2S_3 having a molar ratio of 1:2:1.

The crystal structure of laffittite is a superstructure based upon the PbS structure. Metal-sulfur bonds form a hexagonal ring of one formula unit. The hexagonal rings link to each other by sharing all edges forming a sheet parallel to (100). The sheets link up and down by Hg-S and Ag-S bonds to form a three-dimensional network. As has the usual trigonal coordination by 3S (As-S = 2.26\AA , avg.). Ag has (3 + 1)S coordination: Ag-S = 2.51, 2.52, 2.60 and 2.89\AA . The Hg coordination group is a distorted tetrahedron: Hg-S = 2.42, 2.51, 2.71, and 2.73\AA . The structure is closely related to that of marrite, PbAgAsS_3 .

Description and synthesis

Introduction

The rare mineral laffittite, AgHgAsS_3 , was first described by Johan *et al.* (1974¹) from the Jas Roux mine, Hautes Alpes, France. As far as we know, laffittite has not been reported from any other locality, and their work is the only report which has appeared on this mineral. They reported that laffittite occurred in grains up to 0.2 mm in dolomitic rock associated with routhierite, realgar, stibnite, pierrotite, smithite, sphalerite and pyrite.

During an investigation of a museum specimen from Nevada, the authors recognized a small dark red grain among getchellite crystals, and subsequent X-ray diffraction study and chemical analysis revealed it to be laffittite. We present here some mineralogical data, a method of synthesis, and new crystal data including a complete structure analysis.

Mineralogy

Laffittite was found in a Smithsonian Museum of Natural History specimen (#134796) labelled getchellite, from the Getchell mine, Humboldt County, Nevada. The specimen, about $12 \times 9 \times 6$ cm, is a large mass of orpiment, in which getchellite veinlets are prominent. Laffittite occurs in anhedral grains about 1 mm in maximum length. The grains are usually surrounded by getchellite and/or orpiment. Other associated minerals include realgar, stibnite which is commonly observed as inclusions in orpiment, and rarely sphalerite. The typical mineral assemblage can be seen in Figure 1.

Laffittite is dark red in color and is darker than getchellite. The mineral has adamantine luster and the streak is brownish red. In reflected light in air, laffittite is clearly birefractant, from light bluish gray with an olive tint resembling tetrahedrite, to dark bluish gray with an olive tint. Although the mineral is strongly anisotropic, this is obscured by its strong brilliant red internal reflection. These optical properties resemble those reported for laffittite in the
