**ABSTRACT**

Refractory oxide melts of the binary system MgO-Al<sub>2</sub>O<sub>3</sub> have been studied by molecular dynamics simulation using an advanced ionic interaction model derived from first-principles. The simulations reproduce well experimental densities, structure factors, and transport properties. Anomalous behavior of the latter was observed as a function of melt composition. The minimum in the Al self-diffusion and the respective maximum in the shear viscosity around MgAl<sub>4</sub>O<sub>7</sub> composition are explained by structural changes in the melt.
