**ABSTRACT**

Sulfate is traditionally considered to have retrograde solubility in aqueous solutions. However, our recent hydrothermal diamond-anvil cell (HDAC) experiments have shown that the solubility of Na$_2$SO$_4$ changes from retrograde to prograde in the presence of silica, leading to the formation of sulfate-rich solutions at high temperatures, in line with observations on natural geofluids. In this study, we use synthetic inclusions of fused silica capillary capsules containing saturated Na$_2$SO$_4$ solutions and Na$_2$SO$_4$ crystals to quantitatively investigate the solubility of Na$_2$SO$_4$ at different temperatures in the Na$_2$SO$_4$-SiO$_2$-H$_2$O system. Sulfate concentrations were measured using Raman spectroscopy and calibrated using Cs$_2$SO$_4$ solutions with known concentrations. The solubility of crystalline Na$_2$SO$_4$ dropped slightly when heated from 50 to 225 °C and dramatically from 225 to 313 °C. At 313 °C, the Na$_2$SO$_4$ crystals began to melt, forming immiscible sulfate melt coexisting with the aqueous solution, with or without solid Na$_2$SO$_4$. With the formation of sulfate melt, the solubility of Na$_2$SO$_4$ was reversed to prograde (i.e., solubility increased considerably with increasing temperatures). The solubility of Na$_2$SO$_4$ in the measured solution was significantly higher than that predicted in the absence of SiO$_2$ over the entire temperature range (except for temperatures around 313 °C). This indicates that the presence of SiO$_2$ greatly changes the dissolution behavior of Na$_2$SO$_4$, which may be caused by the formation of a sulfate–silicate intermediates such as Si(OH)$_4$SO$_4$$^{2–}$.

Considering that most crustal fluids are silica-saturated, the solubility curve of Na$_2$SO$_4$ obtained in this study can better reflect the characteristics of geofluids when compared to that of Na$_2$SO$_4$-H$_2$O binary system. At temperatures of 313–425 °C, the solubility of Na$_2$SO$_4$ increases with temperature following the function $C_{\text{sulfate}} = -3173.7/T + 5.9301$, where $C_{\text{sulfate}}$ and $T$ represent the solubility of Na$_2$SO$_4$ in mol/kg H$_2$O and temperature in Kelvin, respectively. As an application, this temperature-solubility relationship can be used to evaluate the sulfate contents in fluid inclusions that contain sulfate daughter minerals, based on the temperature of sulfate disappearance obtained from microthermometric analysis. The sulfate concentrations of the ore-forming fluids of the giant Maoniuping carbonatite-related rare earth element (REE) deposit (southwest China) were calculated to be 4.67–4.81 m (mol/kg H$_2$O). These sulfate concentrations were then used as internal standards to calibrate the previously reported semi-quantitative results of laser ablation-inductively coupled plasma-mass spectrometry (LA-ICP-MS) analysis of REE-forming stage fluid inclusions at this deposit. The calculated Ce concentrations in the REE-mineralizing fluid range from 0.42 to 0.49 wt%. The high fluid REE contents suggest that the sulfate-rich fluids are ideal solvents for REE transport.

**INTRODUCTION**

Sulfate is the second most abundant solute in seawater and widely exists in the crustal mantle fluids and extraterrestrial aqueous environments, such as the surface of Mars and Europa (Chipera and Vaniman 2007; McCord et al. 1998). Sulfate is abundant in some hydrothermal systems related to ore formation, such as volcanogenic massive sulfide (VMS) deposits (Yang et al. 2018) and copper porphyry deposits (Sun et al. 2013). Furthermore, syn-ore fluid inclusions containing sulfate daughter minerals have been reported in carbonatite-related rare earth element (REE) deposits, such as the world-class Bayan Obo in northern China (Xie et al. 2019) and the Maoniuping and Lizhuang in southwestern China (Xie et al. 2015). However, the presence of sulfate-rich geofluids contradicts the knowledge that sulfate salts have retrograde solubility, which would lead to low concentrations of dissolved sulfate in high-temperature solutions (Seward et al. 2014).

Our recent study shows that the presence of dissolved silica is a key to changing the temperature dependence of sulfate
