Components				
NaAlSiO ₄	0.90(1)	0.66(4)	0.62(2)	0.59(2)
Mg ₂ SiO ₄	0.00(0)	0.00(2)	0.00(0)	0.00(0)
Fe ₂ SiO ₄	0.00(0)	0.00(0)	0.02(1)	0.00(0)
MgAl ₂ O ₄	0.00(0)	0.28(2)	0.19(1)	0.20(1)
FeAl ₂ O ₄	0.00(0)	0.00(0)	0.10(1)	0.14(1)
Fe ₃ O ₄	0.00(0)	0.00(0)	0.04(1)	0.03(1)
□Al _{8/3} O ₄	0.04(1)	0.00(2)	0.00(1)	0.00(2)
□Si ₂ O ₄	0.05(1)	0.06(3)	0.03(1)	0.04(1)

Components were calculated as follows.

1. Na, Al and Si form NaAlSiO₄ component.
2. Mg and remaining Al form MgAl₂O₄ component.
3. In case of excess Mg and excess Si, Mg₂SiO₄ component is formed.
4. In case of excess Si, □Si₂O₄ component is formed.
5. In case of excess Al and presence of Fe²⁺, FeAl₂O₄ component is formed.
6. Fe³⁺ and remaining Fe²⁺ form Fe²⁺Fe³⁺₂O₄ component.
7. In case or excess Fe²⁺ and Si, Fe₂SiO₄ component is formed.
8. In case of excess Al or Fe³⁺, □Al_{8/3}O₄ or □Fe³⁺_{8/3}O₄ components are formed.

$$R_{\text{int}} = \frac{\sum | |F_o|^2 - |F_o|^2(\text{mean}) |}{\sum |F_o|^2}, R1 = \frac{\sum | |F_o| - |F_c| |}{\sum |F_o|}, wR2 = \frac{\sum w (|F_o|^2 - |F_c|^2)^2 / \sum |F_o|^2 \}^{1/2}, S_{\text{fit}} = \{ \sum w (|F_o|^2 - |F_c|^2)^2 / (n - p) \}^{1/2}, w = 1 / \{ \sigma^2 (|F_o|^2) + (a \times P)^2 + b \times P \} \text{ and } P = ([\text{Maximum} (|F_o|^2 \text{ or } 0)] + 2 \times |F_c|^2) / 3,$$

where F_o and F_c are the observed and calculated structure factors, respectively. w , n and p , are the statistical weight, the number of reflections and the total number of parameters refined, respectively. Maximum (F_o^2 or 0) is replaced by 0 when the observed F_o^2 value is negative because the background is higher than the peak.

*Chemical composition from EPMA.

§In refinement strategy 1, the site occupancies and total atomic concentrations are fixed according to the end members molar fractions reported in Table OM1. In refinement strategy 2, the site occupancies and total atomic concentrations were refined using chemical restraints from EPMA data.

Table OM5. Summary of site occupancy factors for each cation in the A, B1 and B2 sites and total atomic concentration refined or fixed in different refinement strategies and experimental.

^a In refinement strategy 1, the site occupancies and total atomic concentrations are fixed according to the end members molar fractions reported in Table OM1. In refinement strategy 2, the site occupancies and total atomic concentrations were refined using chemical restraints from EPMA data. Uncertainties determined in the refinement strategy 2 are determined using the full covariance matrix to account for the high correlation coefficients between site occupancy factors. Numbers in italics were fixed during the refinement.

Table OM6. Results of structure analyses of crystals (H5477, S7759, and H5469). All values are reported in Å.

^a In refinement strategy 1, the site occupancies and total atomic concentrations are fixed according to the end members molar fractions reported in Table 2. In refinement strategy 2, the site occupancies and total atomic concentrations were refined using chemical restraints from EPMA data. Uncertainties determined in the refinement strategy 2 are determined using the full covariance matrix to account for the high correlation coefficients between site occupancy factors.

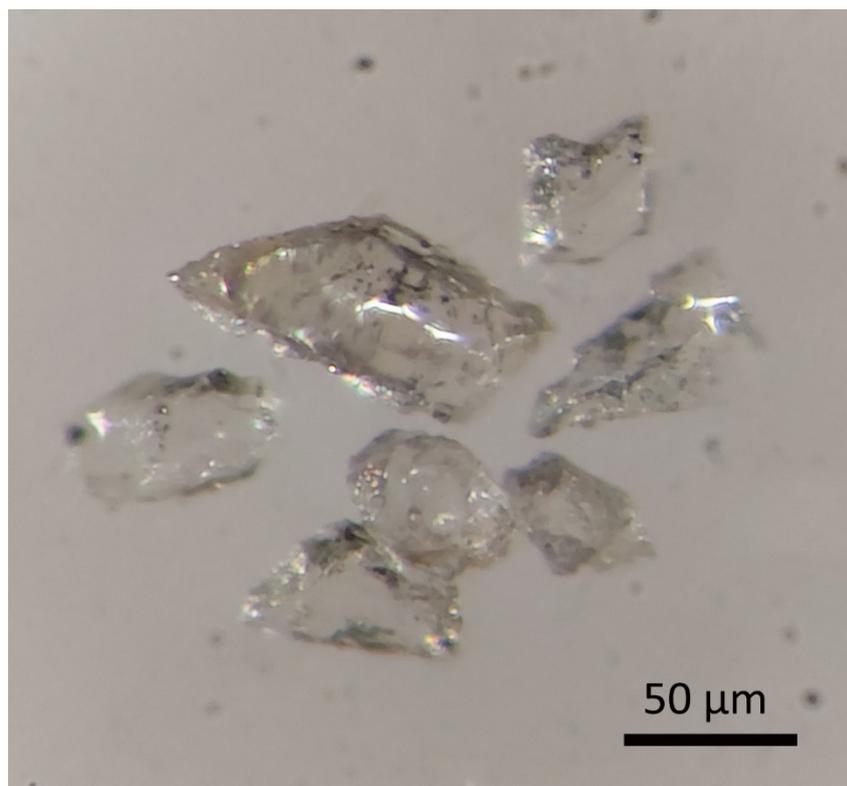

Figure OM1. A photograph of NaAlSiO₄ calcium ferrite single-crystals (H5477).

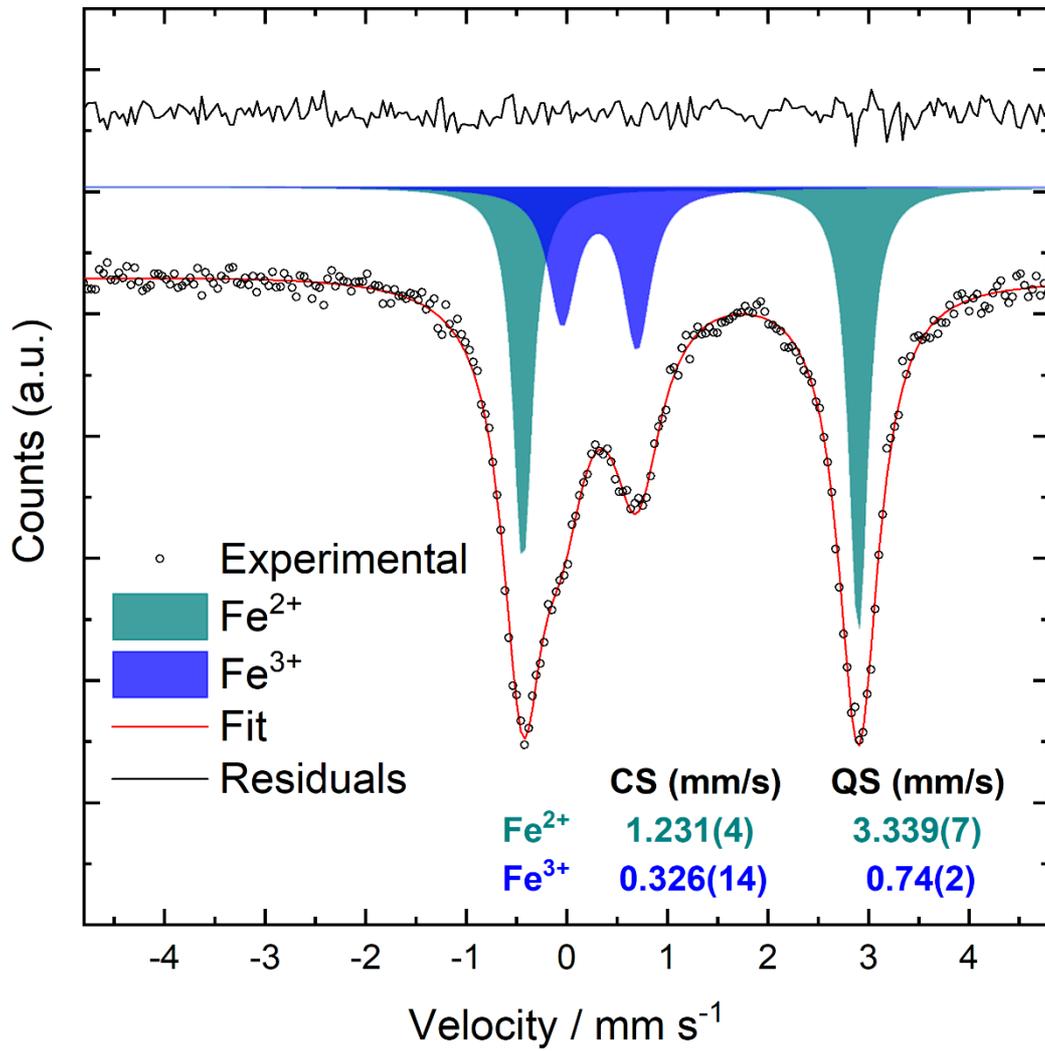

Figure OM2. A Mössbauer spectrum of recovered Fe-bearing calcium ferrite sample (S7760). CS, center shift; QS, quadrupole splitting.

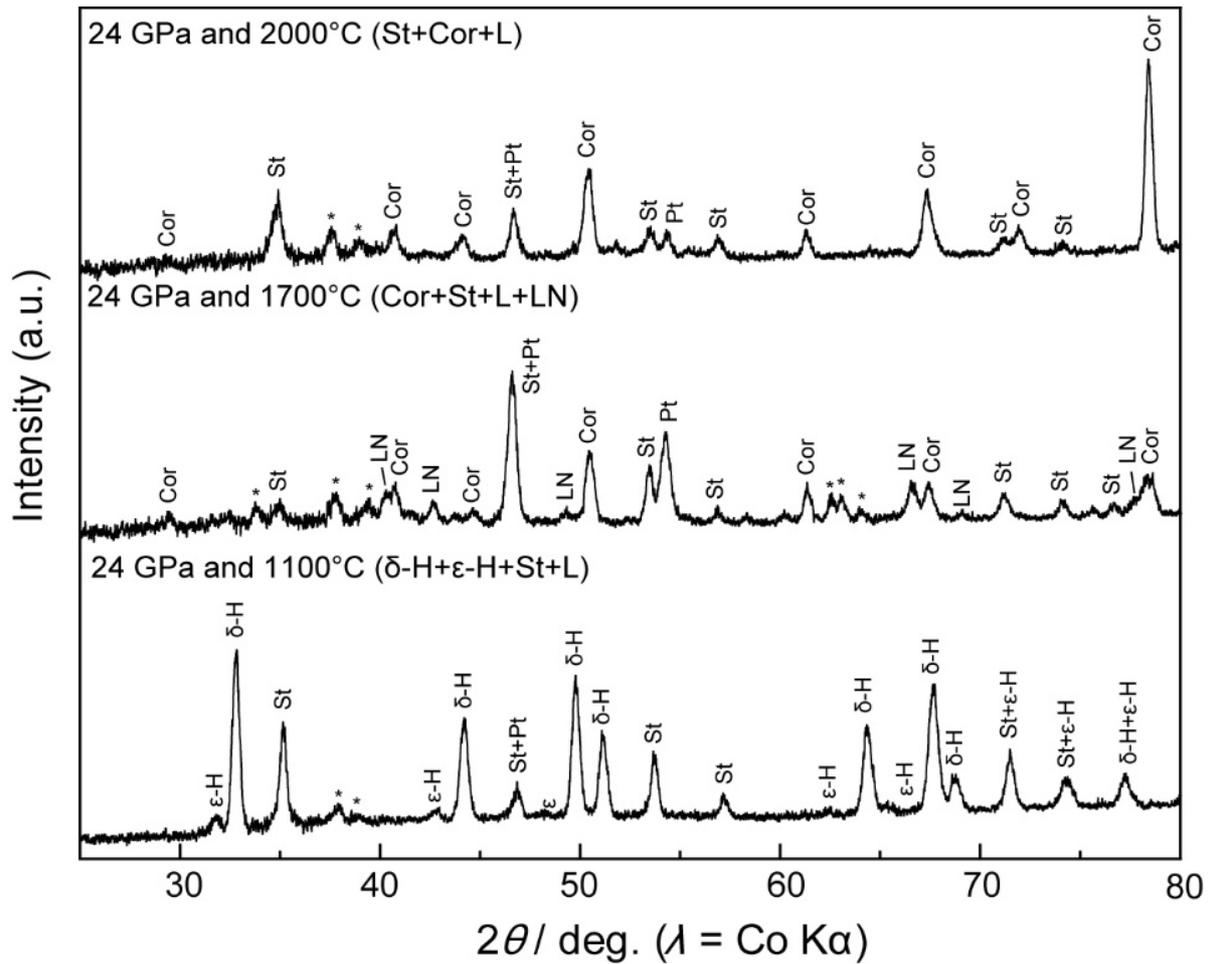

Figure OM3. Representative micro-focus X-ray diffraction patterns of the recovered hydrous samples at 24 GPa and 1100, 1700 and 2000 °C. δ -H, AlOOH-rich hydrous phase δ ; ϵ -H, FeOOH-rich hydrous phase ϵ ; St, stishovite; Cor, corundum; Ln, lithium niobate phase; L, liquid phase; Pt, Pt capsule. Stars (*) are unknown peaks, which are probably from quenched melt (see text).

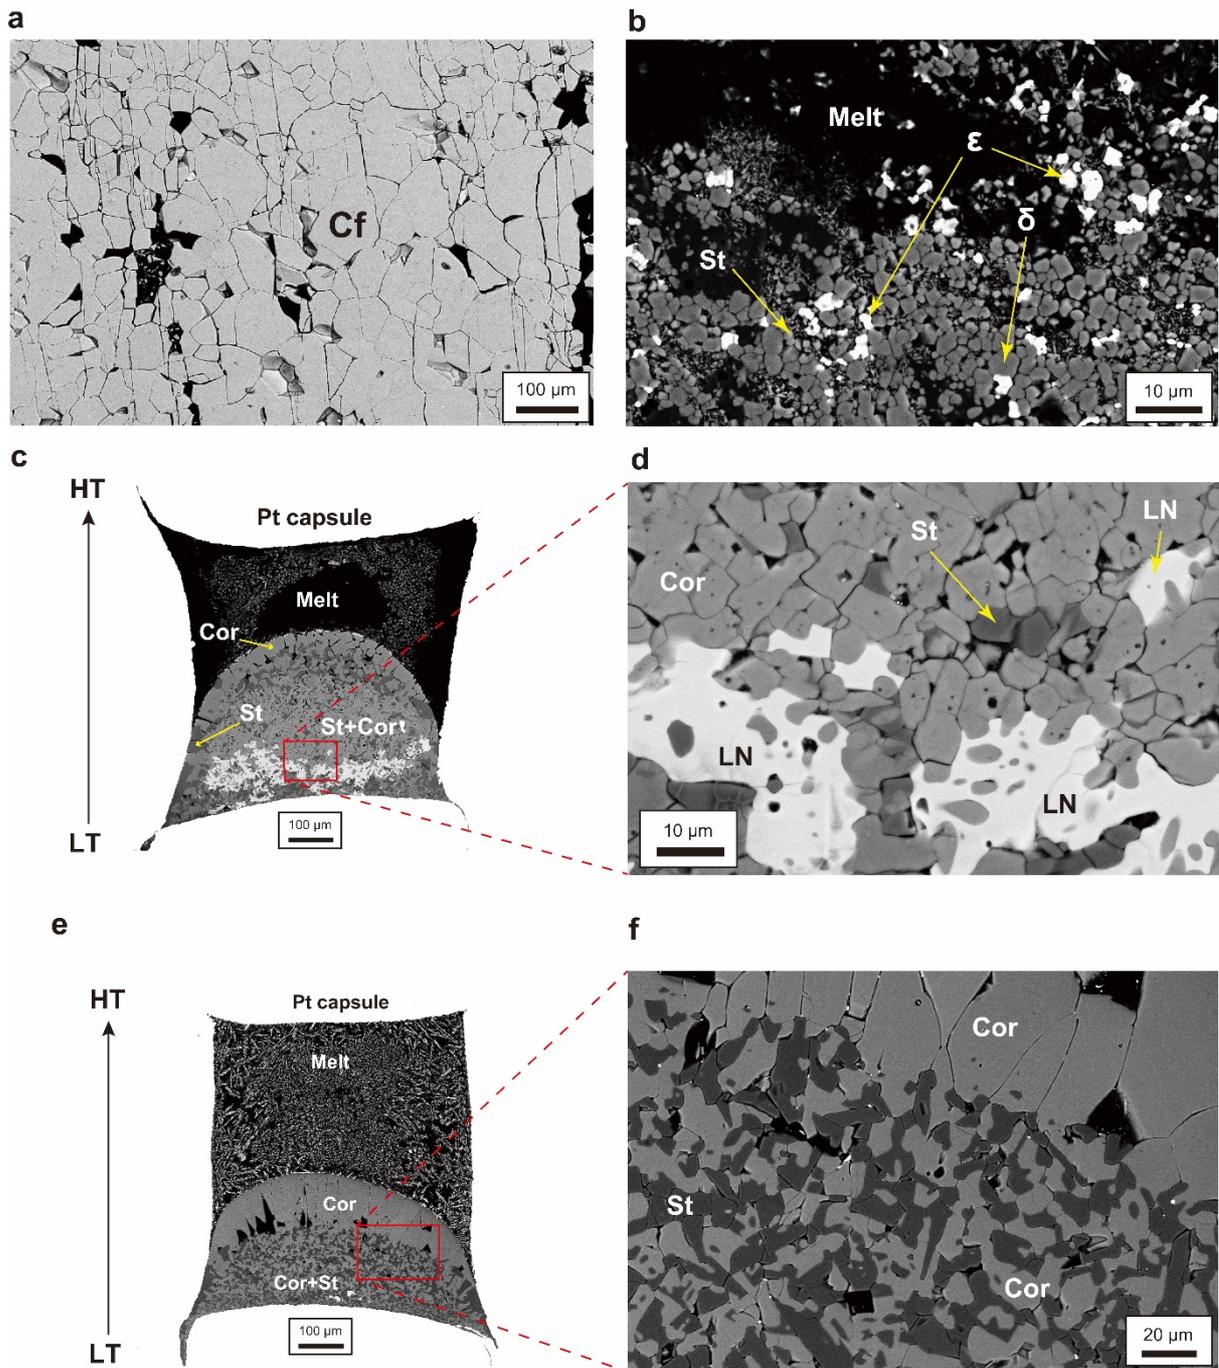

Figure OM4. Representative back-scattered electron images of recovered samples at (a) 23 GPa and 2000 °C in the $\text{NaAlSiO}_4\text{-MgAl}_2\text{O}_4\text{-Fe}_3\text{O}_4$ system (H5469) and (b) 24 GPa and 1100 °C (H5474), (c,d) 24 GPa and 1700 °C (H5462) and (e,f) 24 GPa and 2000 °C (H5471) in the $\text{NaAlSiO}_4\text{-MgAl}_2\text{O}_4\text{-Fe}_3\text{O}_4\text{-H}_2\text{O}$ system. Cf, calcium ferrite phase; δ , AlOOH -rich hydrous phase; ϵ , FeOOH -rich hydrous phase; St, stishovite; Cor, corundum; LN, lithium niobate phase; HT, higher temperature; LT, lower temperature.

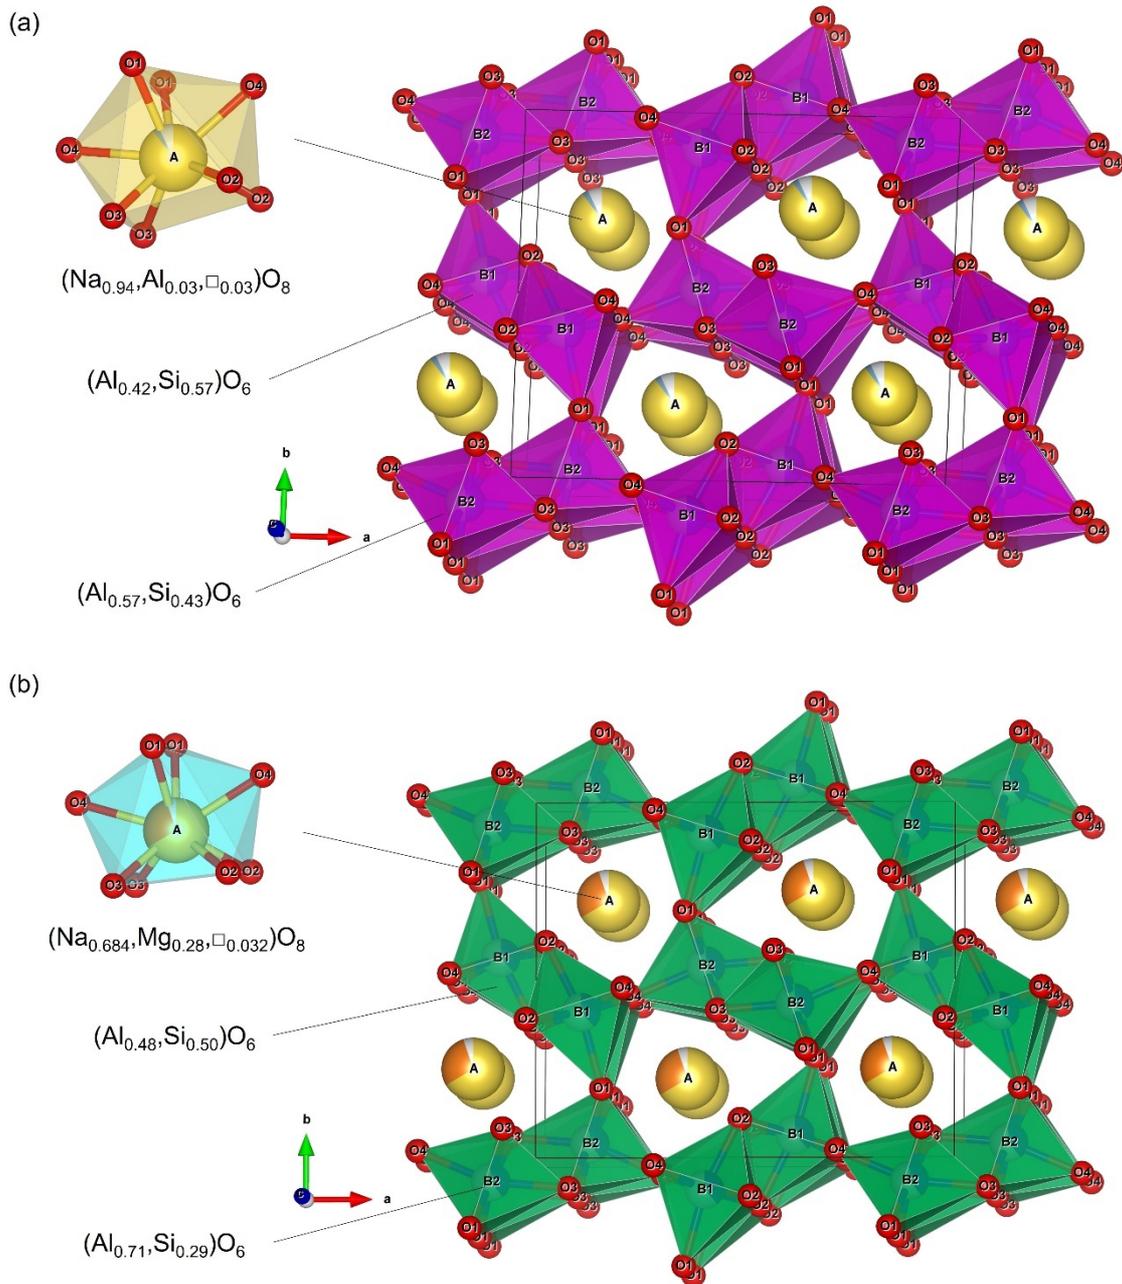

Figure OM5. Crystal structures of (a) $\text{Na}_{0.90(1)}\text{Al}_{1.03(2)}\text{Si}_{1.00(2)}\text{O}_4$, (b) $\text{Na}_{0.66(4)}\text{Mg}_{0.28(4)}\text{Al}_{1.22(3)}\text{Si}_{0.78(3)}\text{O}_4$ for H5477 and S7759, respectively. Different color areas in the spheres of A, B1 and B2 sites show the ratio of constituent atoms. \square : vacancy. The crystal structure was drawn with the VESTA software (Momma and Izumi, 2011).

Detailed description of analytical methods

All phases in the recovered samples were first identified using a micro-focused X-ray diffractometer (Bruker, D8 DISCOVER) equipped with an I μ S source of Co-K α radiation operated at 40 kV and 500 μ A, and a two-dimensional solid-state detector (VÅNTEC500). The compositions of the phases in the recovered samples were measured using an electron microprobe analyzer (EPMA) with wavelength-dispersive spectrometers (JEOL, JXA-8200), operated at an accelerating voltage and probe current of 15 kV and 5 nA, respectively. The samples were generally measured for acquisition times of 10 s, except for run products from H5469, H5477 and S7759, which were measured for 5, 10 and 20 s each. Enstatite was used as standard for Mg and Si, corundum for Al, albite for Na and iron metal for Fe. Sample textures were observed using a field-emission-type scanning electron microscope (SEM) (Zeiss LEO 1530 Gemini) with a detector for backscattered electron (BSE) imaging and an energy dispersive X-ray spectrometer (Oxford X-Max^N).

The oxidation state of iron in the recovered Fe-bearing Cf-type phases was determined by Mössbauer spectroscopy. A mosaic of large inclusion free single-crystals of the Cf-type phase with a total dimension of about 500 μ m in diameter and 100 μ m in height was prepared and sandwiched between plastic films. A piece of Ta foil with a 500 μ m hole was placed in front of the sample mosaic to select the desired area to measure. Mössbauer spectra were obtained at room temperature in transmission mode on a constant acceleration Mössbauer spectrometer with a nominal 370 MBq ⁵⁷Co high specific activity source in a 12- μ m-thick Rh matrix. The velocities in all spectra were calibrated using a reference spectrum of a 25- μ m-thick α -Fe foil certified by National Bureau of Standards (now referred to as the National Institute of Standards and Technology, standard reference material no. 1541) at room temperature. Spectra were collected for 4-6 days and fitted with full transmission integrals using the MossA software (Prescher et al. 2012). Two pseudo-Voigt doublets were used to fit the contribution of Fe²⁺ and Fe³⁺ in the Cf-type phases to the transmission spectra.

High-quality crystals of Cf-type phases with no inclusion and sharp optical extinction checked under a polarizing microscope were mounted on glass fibers and analyzed on a kappa-geometry Xcalibur single-crystal diffractometer (Rigaku, Oxford

Diffraction). The diffractometer was equipped with graphite-monochromatized $\text{MoK}\alpha$ radiation operated at 50 kV and 40 mA and a Sapphire2 CCD detector. Intensity data were acquired upon ω -scan rotations up to $2\theta_{\text{max}} = 90^\circ$ so that unique reflections in the Laue group mmm were measured with an average redundancy of 5. Integration of intensity, correction for Lorentz and polarization factors, frame scaling and empirical absorption correction using spherical harmonics were carried out using CrysAlisPro (Rigaku, Oxford Diffraction).
