ABSTRACT

Phengitic muscovite- $2M_1$ crystals $[(^{12})(K_{0.88-0.99}Na_{0.01-0.09}Ca_{0.00-0.06}Ba_{0.00-0.01})^{6}(Al_{1.64-1.88}Fe_{0.06-0.29}^{3+}Fe_{0.01-0.16}^{3+}Mg_{0.00-0.16}Mn_{0.00-0.07}Ti_{0.00-0.06})^{4}(Si_{2.87-3.30}Al_{0.70-1.13})(OH)_{1.56-2.07}F_{0.00-0.41}O_{9.91-10.25}]$ from pegmatites and peraluminous granites were refined to investigate the influence of phengitic substitution on the mica structure. Single-crystal X-ray diffraction data were collected for eleven crystals in the $C2/c$ space-group (agreement factor $2.1\% \leq R_{obs} \leq 3.9\%$). Tetrahedral Si and Al cation disorder was found for each sample, with the mean tetrahedral cation-oxygen distances ranging from $1.639 \text{ \AA} \leq \langle T1-O \rangle \leq 1.647 \text{ \AA}$ and $1.640 \text{ \AA} \leq \langle T2-O \rangle \leq 1.646 \text{ \AA}$. As phengitic substitution increases, the octahedral sheet expands and requires a less distorted (more hexagonal) tetrahedral ring ($7.70^\circ \leq \alpha \leq 11.38^\circ$) and low corrugation of the basal O plane ($0.1796 \text{ \AA} \leq \Delta z \leq 0.2296 \text{ \AA}$). The electron density at the M2 site is greater than that required for the ideal muscovite- $2M_1$ structure, and a small excess of electron density is found in the M1 site. The inner sixfold coordination of the interlayer (A) cation is elongated along c^* , which is consistent with the high α values and the long A-O11 bond length.
